June 2012

CATTLE FINISHING NET RETURNS

This article discusses recent trends in feeding cost of gain and cattle finishing profitability. Several sources of data were used to compute the cattle finishing net return series discussed below. Feeder and fed cattle prices were obtained from the seasonal cattle price spreadsheet updated monthly by Kevin Dhuyvetter. Average daily gain, feed conversion, days on feed, in weight, out weight, and feeding cost of gain were obtained from monthly issues of the *Focus on Feedlots* newsletter. Interest rates were obtained from the Kansas Federal Reserve Bank of Kansas City.

Figure 1 presents monthly steer finishing net returns from January 2000 to May 2012. It is important to note that net returns were computed using closeout months rather than placement months. Net return per head for 2011 was approximately \$0 compared to a net return per head for 2010 of \$52, and losses of \$105 and \$117 per head in 2008 and 2009, respectively. Net losses per head in January, February, and March of this year were \$59, \$3, and \$19, respectively. Net losses per head in April and May of this year were approximately \$146 and \$131, respectively, the largest losses since March 2009.

Figure 2 illustrates fed price and breakeven prices from January 2000 on. The breakeven prices starting in June 2012 are forecasted. Breakeven prices for June closeouts are expected to range from \$132 to \$135 per cwt. At this breakeven price, loss per head is

expected to exceed \$150 per head. Breakeven prices for July through December closeouts are expected to range from \$134 to \$137. It is important to note that breakeven prices are highly dependent on the corn market, which has been highly volatile in the last few months. Using current corn price projections, feeding cost of gain is expected to stay above \$100 for the rest of the year.

Correlation coefficients can be used to examine the relationship between net returns, feeding cost of gain, and the feeder to fed cattle price ratio. Correlation is a statistical measure of how variables move together and is bounded by -1.0 and 1.0. A value of -1.0 indicates two variables move together perfectly, but in opposite directions, while a value of 1.0 indicates two variables move up and down together proportionally. Values close to zero indicate two variables have little relationship to each other.

Net returns are significant and negatively correlated with feeding cost of gain ($r = -0.244$). Figure 3 illustrates monthly feeding cost of gain from January 2000 to May 2012. Feeding cost of gain has been above \$100 per cwt since August of 2011. Feeding cost of gain for the third and fourth quarters of 2012 is expected to range from \$104 to \$107. If corn prices were to drop below \$6.00, which is quite a bit below current projections, feeding cost of gain would drop below \$100. Feeding cost of gain is sensitive to changes in feed conversions, corn prices, and alfalfa prices. Regression analysis

was used to examine the relationship between feeding cost of gain and feed conversion, corn prices, and alfalfa prices. Results are as follows: each 0.10 increase in feed conversion increases feeding cost of gain by \$1.02 per cwt, each 0.10 per bushel increase in corn prices increases feeding cost of gain by \$1.11 per cwt, and each \$5 per ton increase in alfalfa prices increases feeding cost of gain by \$0.34 per cwt.

Net returns are also significant and negatively correlated with the feeder to fed cattle price ratio ($r = -0.815$). The strong correlation between these variables reveals the importance of this price ratio to net returns. The feeder to fed cattle price ratio is illustrated in figure 4. The average price ratio since 2000 is 1.16. Of course, it is not possible to fully anticipate what fed cattle prices will be when purchasing feeder cattle. Large deviations from the mean price ratio indicate periods for which expected and actual fed cattle prices were quite different. The closeout months with ratios below 1.00 exhibited cattle net returns averaging \$178 per

head while the closeout months with ratios above 1.40 exhibited cattle finishing losses averaging \$163 per head. The feeder to fed cattle price ratios during the first quarter of 2012 averaged 1.08. The feeder to fed cattle ratio for April and May was 1.21 and 1.20, respectively. The feeder to fed cattle price ratio for June closeouts is expected to range from 1.24 to 1.27, which is above the long-run average. This relatively high ratio is certainly contributing to the expected large loss.

This article discussed recent trends in feeding cost of gain and cattle finishing net returns. Net return information for beef cow and backgrounding operations is available on the Kansas Farm Management Association web site (www.agmanager.info/kfma).
